Datt

Outline

Hash functions

Base 58

Blocks, Transactions, Addresses

Elliptic Curves

ECDSA: Private keys, Public keys, Signatures

Bonus: Encryption, HMAC

github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

Cryptographic Hash Functions

- data → hash(data)
- Hash value is always the same number of bytes (e.g. 20, or 32)
- Fast: Can "easily" compute hash from data – difficulty is O(N)
- Irreversible: Cannot compute data from its hash
- Sensitive: Changing the data changes the hash
- Unique: Cannot find to datas with same hash
- "Random": All bits are equally likely to be 1 or 0

Ryan X. Charles
Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

Cryptographic Hash Functions

- md5 ← thoroughly broken
- sha1 ← known to be weak
- sha2 (sha256, sha384, sha512) ← sha256 **used by bitcoin**
- ripemd160 ← **used by bitcoin**

Ryan X. Charles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt
Base 58

- Base 10: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9
- Base 2 (binary): 0, 1
- Base 16 (hex): 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, a, b, c, d, e, f
- Base 64: 0 – 9, a – z, A – Z, and: ' ( ) , - . / : ?
- Base 58: similar to base 64, but only alphanumeric, and **no confusingly similar characters like uppercase i and lowercase L**. Set: 123456789ABCDEFGHJKLMNPQRSTUVWXYZabcdefghijkmnopqrstuvwxyz

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

Base 58 Check

- What if someone is copying a Base 58 value by hand? Would be nice to have a checksum to check for errors ...
- **Base58(Data + hash(data))**
- Base58Check Encode: Find the first four bytes of sha256sha256(data), and append to data, then Base58 encode
- Base58Check Decode: Base58 decode, then parse data as everything but the last four bytes, and confirm that the last four bytes equal the first four bytes of sha256sha256(data)

Ryan X. Charles
Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

Base 58 Check

- Data: "example data"
- Base58Check: DXjqxEXcqRyEsbyWmsG2a8
- Data: "example data 2"
- Base58Check: 5D71bmikb468yPvud1vYLXbbH
- Data: "example data 3"
- Base58Check: 5D71bmikb468yPvud1ve55ADa

github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt
Addresses

- An address is the sha256ripemd160 hash of a public key (usually a compressed public key)
- When displayed visually, addresses are displayed in base58check notation. They are also prepended with a 0x00 byte (if they are pubkeyhash addresses), or with a 0x05 (if they are a p2sh address)
- It so happens that when encoded this way, normal addresses always start with a "1" and p2sh addresses always start with a "3"
- Example address: 1343UaYEDYpbHQH2KF24mxTJ9GGXbzrGX9
- Example p2sh: 3GENUmnERtWfQct4NegomUqqtZuzYGPwBS

Some Context on ECDSA

- Bitcoin transactions involve "signing"
  - Technically, transactions don't need to involve signatures, but they almost always do
- ECDSA: Elliptic Curve Digital Signature Algorithm
  - ECDSA can: create a signature from data and privkey
  - ECDSA can: validate a signature from data and pubkey
- Signatures and public keys occur in transactions (private keys are kept private, of course)
- Bitcoin's core protocol does not use encryption
  - ECDSA is "cryptography", but not "encryption"
- **ECDSA** is based on mathematics of **Elliptic Curves**

Datt

Basic Math: Numbers, Points, Eqns

- A number: 5
- A point: (5, 1)
- An equation: $y = x^2$
- A solution:
  - $y = 4$, $x = 2$
  - Or, (2, 4)

Datt

Elliptic Curves

Points on an EC are solutions to this eqn:
$$y^2 = x^3 + ax + b$$

$$M_3 = M_1 + M_2$$

Datt

Elliptic Curves

- Can define "addition" and "multiplication" of points to get a **field**
- A field is a set of points: X = (x, y)
  - With addition operation: $(x_1, y_1) + (x_2, y_2) \rightarrow (x_3, y_3)$
  - Multiplication defined as: $2 * (x, y) \rightarrow (x, y) + (x, y)$
  - Commutative: $(x_1, y_1) + (x_2, y_2) = (x_2, y_2) + (x_1, y_1)$
  - Associative: $\mathbf{(}(x_1, y_1) + (x_2, y_2)\mathbf{)} + (x_3, y_3) = (x_1, y_1) + \mathbf{(}(x_2, y_2) + (x_3, y_3)\mathbf{)}$
  - ...and all the other properties of a mathematical field

Datt

Elliptic Curve Cryptography

- Cryptography you can do with elliptic curves:
  - **Sign and verify** data ← **used by bitcoin**
  - Encrypt and decrypt data ← not used by bitcoin
- EC Crypto is based on **finite fields** – not continuous curves as you might think
  - The same equations and operations apply – but cannot be visualized as a curve
- Confusingly, finite fields do not look like curves

Ryan X. Charles
Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt
Elliptic Curve Cryptography

- Mathematically possible to subtract:
- If A + B = C, then B = C – A
- ...but this is computationally impracticable: equivalent to solving Discrete Logarithm Problem
- A = 2 B = B + B ...
- If you know "A" and "2", you can only find B from brute force – try every value until you get it.
- Quantum computers can solve discrete log problem – problem for EC crypto!

Datt

secp256k1

- The curve used by bitcoin – specified by curve and finite field parameters: (a, b, p, n, G, h)
- $y^2 = x^3 + ax + b$ (as always for elliptic curves)
- a = 0, b = 7
- $p = 2^{256} - 2^{32} - 2^9 - 2^8 - 2^7 - 2^6 - 2^4 - 1$
- n = 115792089237316195423570985008687907852837564279074904382605163141518161494337
- G = (55066263022277343669578718895168534326250603453777594175500187360389116729240, 32670510020758816978083085130507043184471273380659243275938904335757337482424)
- h = 1
- N: "order" = "largest private key"
- G: "base point"

Datt

Private Keys and Public Keys

- A private key is a number in the range (0, N)
- A public key is a private key times G
- Public Key = Private Key * Base Point
- P = pG
- If p = 5, then P = 5G, or:
  - P = 5 * (x, y)
    - P = (21505829891763648114329055987619236494102133314575206970830385799158076338148, 98003708678762621233683240503080860129026887322874138805529884920309963580118)
- Never use "5" as a private key! Generate a random number in range (0, N)

Datt

ECDSA

- Given private key and data, need to produce a signature
- Given signature, data, and public key, need to confirm that signature is for corresponding private key
- ECDSA: Elliptic Curve Digital Signature Algorithm
- An ECDSA signature consists of two numbers, r and s. Although a pair of numbers, it is not a point.

Ryan X. Charles
Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

ECDSA - Sign

1. Calculate $e = \text{HASH}(m)$, where HASH is a cryptographic hash function, such as SHA-2.
2. Let z be the L_n leftmost bits of e, where L_n is the bit length of the group order n.
3. Select a **cryptographically secure random** integer k from $[1, n-1]$.
4. Calculate the curve point $(x_1, y_1) = k \times G$.
5. Calculate $r = x_1 \bmod n$. If $r = 0$, go back to step 3.
6. Calculate $s = k^{-1}(z + rd_A) \bmod n$. If $s = 0$, go back to step 3.
7. The signature is the pair (r, s).

- Pseudocode credit: Wikipedia
- (Caveat: Not all details here – do not rely on for implementation)

Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

# ECDSA - Verify

1. Check that Q_A is not equal to the identity element O, and its coordinates are otherwise valid
2. Check that Q_A lies on the curve
3. Check that $n \times Q_A = O$

After that, Bob follows these steps:

1. Verify that r and s are integers in $[1, n-1]$. If not, the signature is invalid.
2. Calculate $e = \text{HASH}(m)$, where HASH is the same function used in the signature generation.
3. Let z be the L_n leftmost bits of e.
4. Calculate $w = s^{-1} \bmod n$.
5. Calculate $u_1 = zw \bmod n$ and $u_2 = rw \bmod n$.
6. Calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$.
7. The signature is valid if $r \equiv x_1 \pmod{n}$, invalid otherwise.

ECDSA – Extra Details

- It is possible to derive candidate public keys from a signature – which can be compared to the hash of a public key to see if a signature is valid. Makes possible "**Bitcoin Signed Message**"
- Generating a signature involves a random value "k". This value needs to be unpredictable, but can be computed deterministically from the data and the private key – standard for this is **RFC 6979**. This is actually safer than a purely random value, in case your entropy pool is broken. Also helps validate the signature algorithm is working correctly by comparing to known test vectors.

Ryan X. Charles

github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

ECDSA - Summary

- **ECDSA Sign**: Privkey + hash(data) → (r, s)
- **ECDSA Verify**: (r, s) + hash(data) + Pubkey → valid|invalid
- **Cannot derive privke**y from pubkey
- **Cannot derive privkey** from signature
- **Use RFC 6979** – deterministic k

Datt

Conclusion

- Bitcoin does not use encryption
- Bitcoin uses hash functions to identify data (transactions, blocks, addresses)
- Bitcoin uses ECDSA to sign and verify transactions

Ryan X. Charles

Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt
Bonus: Encryption

- Encryption is not a part of the core bitcoin protocol
- However, it is wise to encrypt your private keys when storing on a hard drive
- Almost all encryption protocols are base on AES, a block cipher, which must be combined with a mode of operation, such as CBC, and a MAC
- AES: encrypt a 128 bit block of data
- AES+CBC: encrypt data of any size
- **AES+CBC+HMAC**: encrypt data of any size and know it hasn't been tampered with during transmission
- ... "if you're typing AES into your application, you're doing it wrong" - usually wisest to use standard libraries to encrypt/decrypt to minimize chance of error

Ryan X. Charles
Founder of Datt (datt.co)
twitter.com/ryanxcharles
github.com/ryanxcharles

Code Samples and Slides at:
github.com/ryanxcharles/blockchain-university

Datt

Bonus: HMAC

- It is common to use hash functions as a MAC, or "message authentication code"
- By hashing data and checking the hash, you can be sure data hasn't change during transmission
- To prevent attacks like rainbow tables, hashing is often combined with a key. But some poor constructions, such as simply concatenating key with data, lead to exploits, such as changing data to contain bits of key, or vice versa (see Amazon) [1]
- **HMAC(data, key) = hash(hash(data) + hash(key))** ...plus some other complications, basically
- Protip: If you ever find that you're hashing data and a key to ensure integrity, you should probably be using HMAC and not just a hash

  [1] http://rdist.root.org/2009/05/20/amazon-web-services-signature-vulnerability/

Datt

Homework

- Generate some data of any kind, then run each of these hash functions on the data: sha1, sha256, sha512, sha256sha256, ripemd160, sha256ripemd160
- Generate some data of any kind, then find the Base58check encoded form of that data. Try decoding the data and be sure your get your data back.
- Generate a public key from a private key.
- Sign some data with ECDSA. Verify that the signature is correct.
